

The OICL Pre-Presentation Presentation

1. Ocean Industries Concept Lab

2. SEDNA - Arctic Context

SEDNA ("Safe maritime operations under extreme conditions: the Arctic case") is a research project that is developing an innovative and integrated risk-based approach to safe Arctic navigation, ship design and operation.

Ships and their crews operating in the Arctic face a number of significant safety challenges including:-

- Inherent navigation technology limitations, such as creeping/compass errors and variable GNSS positioning errors, causing bridge teams who lack experience of operating in the Arctic to be at increased risk of making potentially dangerous misjudgements and errors as a result, with potentially serious consequences.
- Lack of accurate navigational information. The presence of ice has a major impact on the safety, operability and efficiency of Arctic operations and navigation. Equipment commercial research has ice forecasting products are not fit for purpose for use on board vessels and have not been adequately verified, validated and optimised for use operationally in strategic ice management. More research is needed to weather routing system available to consider the optimum operation of ships under ice conditions.
- Generic bridge designs unsuited for the region. Vessels operating in the Arctic have bridge designs that are the same in layout and equipment fit as vessels operating elsewhere i.e. they are not fit for purpose for Arctic operations. Operating a ship in Arctic waters is complex and hazardous, the difficulties of navigating a vessel in the harsh environment of the Arctic, with its extreme weather and the presence of ice, put the crew under severe stress. Being overwhelmed by information from many different sources exacerbates this experience leading to poor situational awareness and decision making. Approaches to navigation, and these continue to occur despite the development and availability of technologies that aim to improve situational awareness and decision making. When focusing on the bridge, the information layers that ship's crews are presented with are often fragmented and inconsistent, leading to a lack of a coherent picture of the situation.
- Ship navigation teams without specialist Arctic navigation knowledge. More and more vessels navigating in Arctic waters are not crewed by bridge teams with Arctic navigation experience. Arctic navigation is a highly specialised and complex activity that demands particular skills from bridge crews to be safe. In the absence of specialist Arctic navigation knowledge, the risk profile for vessels operating in the Arctic is significantly increased.

To address these safety challenges, SEDNA will develop the Safe Arctic Bridge, a human-centred operational environment for the ice-going ship bridge using augmented reality technology to provide improved situational awareness and decision making whilst enabling integration with new key information layers developed by the project using innovative big data management techniques.

2. Augmented Reality

reality

augmented reality

virtual reality

the hololens uses additive project to add layers of information on top of the world we already see. it has on board speakers, and tracks the user's head and simple gestures.

What we have:

- inside out head tracking
- additive projections
- personal & spatial sound
- on-board processing
- short battery life
- small field of view
- heavy
- poor interactions

What we will have:

- inside out + outside in head tracking
- eye/gaze tracking
- additive projections
- personal & spatial sound
- distributed processing
- long battery life
- wide field of view
- light weight
- robust interactions

AUGMENTED BRIDGE

EXPLORING USER EXPERIENCE ARCHITECTURE
FOR AUGMENTED REALITY ON SHIP BRIDGES

GUSTAV REFSNES & CHRISTOPHER PEARSELL-ROSS

Hello my name is Gustav and this is Chris - and we'll be sharing with you our project - Augmented Bridge - exploring user experience architecture for augmented reality on ship bridges.

CONTEXT + PROBLEM AREA

USER EXPERIENCE ARCHITECTURE

WORKFLOW + GUIDELINES

REFLECTIONS

We're going to share with you our project, a UX architecture system, but we actually feel some of our strongest contributions this semester have been to experiment with workflow, and to develop some guidelines for other designers, so we're going to talk a bit about that as well.

CONTEXT + PROBLEM AREA

First, the context and problem area.

"THE KEY CHALLENGE IS HOW TO IMPROVE
THE HUMAN-SYSTEM INTERFACE AND
PROVIDE A MECHANISM TO SUCCESSFULLY
MANAGE THE LARGE AND VARIED
INFORMATION LAYERS"

SEDNA PROJECT

We took as our starting challenge directly from SEDNA:

"the key challenge is how to improve the human-system interface and provide a mechanism to successfully manage the large and varied information layers"

And part of SEDNA's goal is to see how this can be done through the use of Augmented Reality technology.

ICEBREAKER SITE VISIT

We tested this assumption while on a site visit to an icebreaker.

We had the opportunity to tour the ship and spend a long time with the captain and a navigator on the bridge. We learned a lot about life at sea and the realities of navigating in ice.

One key take away from this visit was that the crew relies on their eyes and their experience more than any other tool.

The captain told us "If there were only one thing I could have, it would be more windows."

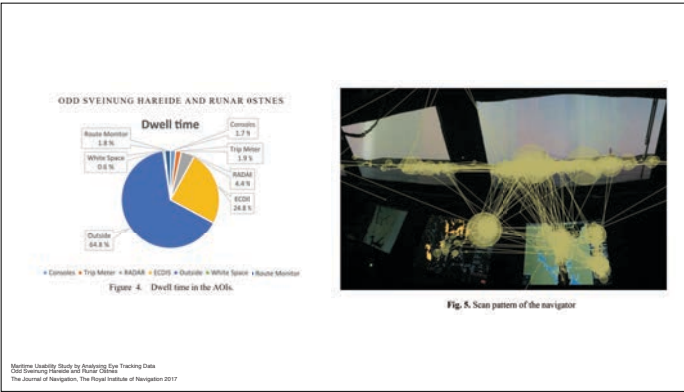

Fig. 5. Scan pattern of the navigator

New research from Odd Hareide and Runar Ostnes supports this statement. Using eye tracking technology, they showed that the information surface navigators rely on most is actually the environment around them.

This presents a huge opportunity, but also major challenges when we understand that this piece of technology has the power to turn everything in the environment into an information surface.

We can live in this reality if we want. Information overload and situational awareness are two sides of the same coin. We can't address one without the other.

WE NEED A STRUCTURE TO
DESIGN WITHIN

Given the importance of clear windows to arctic navigation, and the freedom AR gives us to put information everywhere, we need some kind of structure, some kind of system to design within.

USER EXPERIENCE ARCHITECTURE

This is where we need a User Experience Architecture.

UX Architecture describes the rules and behaviours of the systems that our applications and interactions work within.

A way of thinking about this is to compare designing only a single application, to designing a system for handling multiple applications, their interactions, and the user experience of the overall system.

Except in our case, that system is not a consumer device, it is a 100 meter long arctic-going ship, and all the critical systems and considerations it brings with it.

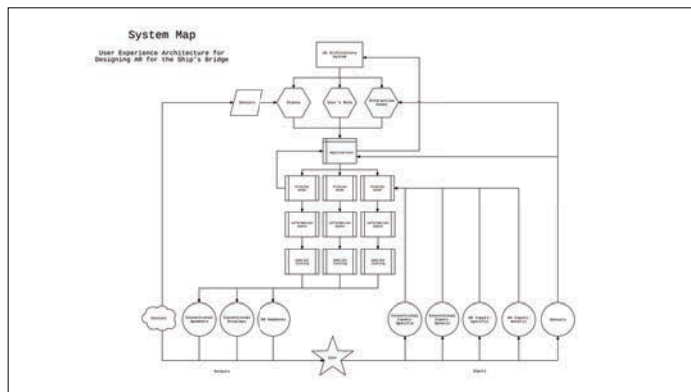

DISCLAIMER: WE ARE NOT DESIGNING SINGLE
INTERFACES. WE ARE DESCRIBING A USER
EXPERIENCE ARCHITECTURE.

Which brings us to an important disclaimer: we are not designing interfaces. we are describing the system that the interfaces work within.

Which brings the question: who are our primary users?

Other designers. The end user is still the crew, and we need to consider their needs at every stage, but for this project we have focused on developing a system and tools for other designers to begin working with augmented reality on the ship bridge.

And the system we have designed looks like this. This is a system map showing what factors influence the overall system behaviour, and what that means for our end users.

Before going into detail about this, we'd like to show you what it could look like.

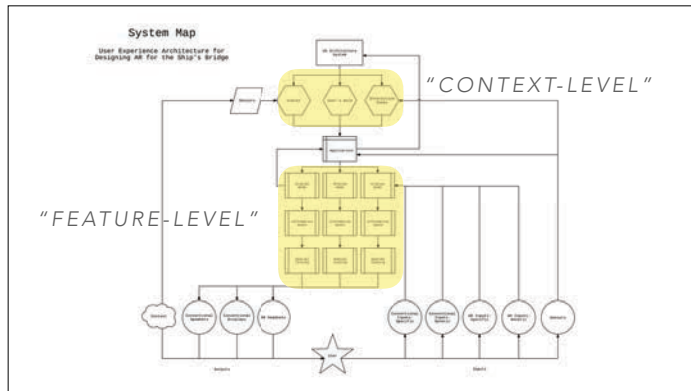

The captain enters the bridge to start his shift. He can see his checklists and reminders in a space suitable space for reading and interaction. As he looks around a critical reminder follows his view.

Next, he moves to the conning station, and the interface adapts. As he checks the horizon for ice, the system notices his presence, and displays environmental information.

Taking his seat at the controls, he adjusts a setting on the console, seeing the interface when and where he needs it.

We see here a sketch of a distributed, responsive, and user-centric system that runs multiple applications in a consistent user experience.

The two parts of this system we will be focusing on today are what we have tentatively called the context-level and feature-level.

These are the core of the system, and they have a large effect on the user experience.

CONTEXT-LEVEL

The context level includes external factors, as well as the internal structure of the bridge and the responsibilities of the crew.

It is made up of **roles**, **states**, and situated interaction **zones**.

Roles describe the individual user's needs, based on their responsibilities on the ship. The system should understand these, and tailor experiences for them. For example, the captain might be responsible for complex manoeuvres, while a junior officer may be responsible for scanning the horizon for traffic.

The ship enters different states, or modes, depending on the environmental conditions. For example, as the sun sets, the ship should enter night mode, and if other ships are close by, it should enter a critical navigation mode.

Lastly, the system should understand the functions of different areas of the bridge, and should adjust what a user sees in their display as they move about. When entering the fore-bridge, conning and engine status might be displayed, while as

The context-level directly affects the behaviour of the individual applications within the system. The bridge is a complex environment with dozens of individual applications, such as the ECDIS, RADAR, wind sensors, and communications systems.

The feature-level of the system describes how these different applications act and respond to the user. It is made up of these highly interrelated parts: information spaces, display modes, responsive behaviours and spatial locking.

INFORMATION SPACES (IN AR)

 Personal Information Space: Information is displayed in a personal space, such as a floating card or a small screen, directly in front of the user.	 Interior Information Space: Information is displayed on a surface within the interior of a space, such as a wall or a screen.	 Window Information Space: Information is displayed on a transparent surface, such as a window or glass, allowing the user to see the environment through it.	 Environmental Information Space: Information is displayed in the environment, such as a floating alert or a large screen, providing a wide area of information.	 Personal Information Space: Information is displayed in a personal space, such as a floating card or a small screen, directly in front of the user.	 Interior Information Space: Information is displayed on a surface within the interior of a space, such as a wall or a screen.	 Window Information Space: Information is displayed on a transparent surface, such as a window or glass, allowing the user to see the environment through it.	 Environmental Information Space: Information is displayed in the environment, such as a floating alert or a large screen, providing a wide area of information.
---	---	--	---	---	---	--	---

Augmented reality gives us a lot of freedom as to where information can be displayed. 4 broad categories of information spaces on the ship bridge include personal, interior, window and environmental.

We saw these spaces in action in our scenario video. Designers will need to consider where their applications are most relevant and useful to the user.

DISPLAY MODES

Applications will also require different display modes, depending on where they are shown, and what level of information a user needs. Individual application designs will need to be flexible and make their functions available in different ways.

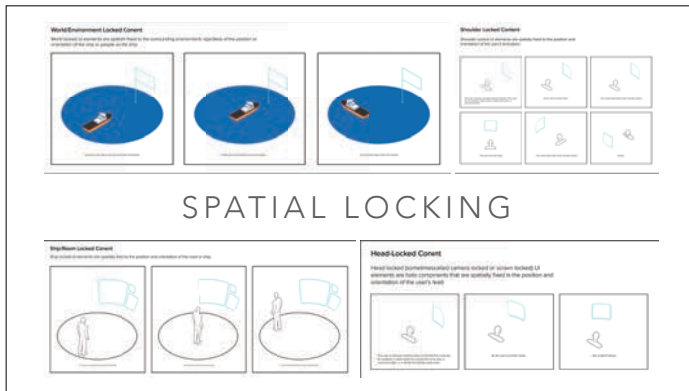

RESPONSIVE BEHAVIOURS

The system should also exhibit responsive behaviours - reacting to user's movements and actions. Grounding designs in solid user insights and research will go a long way to make these behaviours helpful, rather than distracting. For instance, if a user needs to move quickly, the interfaces around them should move to give them a clear view.

An example of this in the video was this situated interaction - as the user approaches the window, the display changes.

Finally, something unique to augmented reality elements is that they need to be situated in space somehow. Spatial locking describes how the position and orientation of AR elements are related to the people, objects and environment in the real world. Designers will need to think in three dimensions, and situate their designs appropriately.

We saw several examples of this in the video, such as the difference between head-locked and shoulder-locked content.

Putting it all together, we see a complex interaction system with the user at it's core. It responds to the changing environment and changing needs of the users, ensuring the information they need is displayed when, where, and how they need it most. Importantly, the system doesn't overwhelm the user with information, but instead supports their situational awareness.

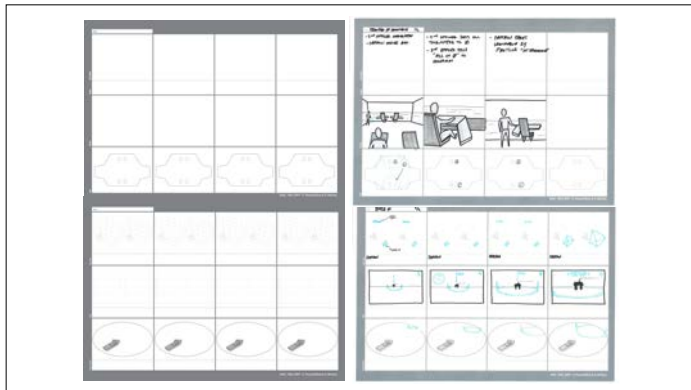

But how did we arrive at this image of the system?

We did this by experimenting using designerly methods, to try and define the outline of the user-experience-architecture.

We have tried to find ways of quickly sketching in 3D. Here, we adapted an existing VR sketching template to our context on the bridge. This allowed us to quickly iterate, sketching in 2D, and experiencing it in 3D.

We also needed to find ways of sketching transitions and work flows quickly. To do this we adapted the Layered Scenario Mapping technique and created these Layered Scenario sketching templates, which let us sketch different information spaces as they change over time. This also forced us to think about all the different parts of the system we identified.

We need to use 3D tools directly. In our case, we used the game engine Unity. We had very little experience using this program, which made it difficult for us to explore interactions. What it did let us do is quickly test how things look in augmented reality, on the HoloLens.

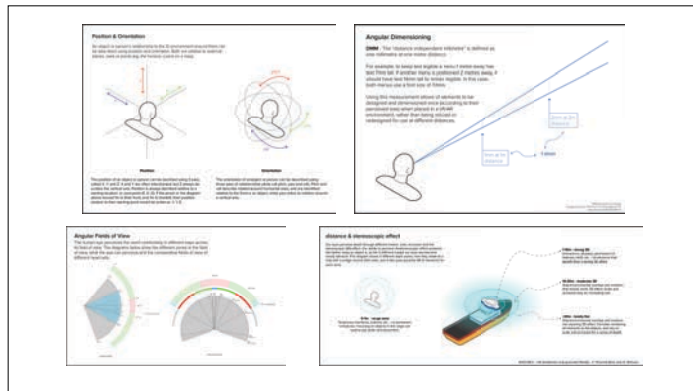

Chris?

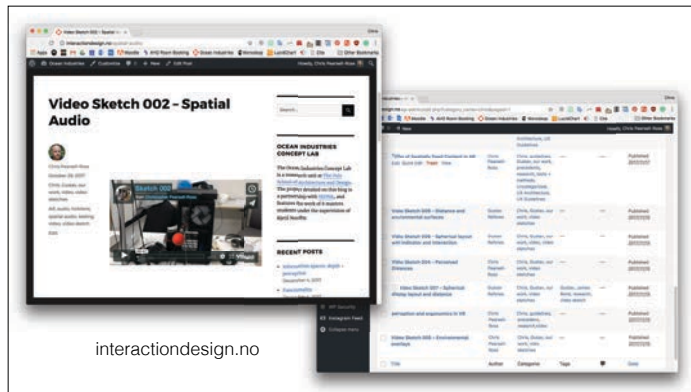

Since AR was such a new experience for us, we were able to focus on testing the fundamental aspects of that experience - perception, distance, scale, colour, and sound.

In this clip, we tested how spatial audio could be used as a personal indicator in alarm systems, highlighting the non-visual opportunities for AR.

All of this experimentation has led to what we think is a deep understanding of what the limitations and opportunities are for designing in AR. We have been trying to make these learnings usable and understandable for others as basic guidelines. But guidelines are not enough - we strongly feel designers need to experience and explore AR for themselves.

This is documented on the blog, interactiondesign.no

All of this has led us to some reflections, probably more will come down the road when we have had a chance to sleep a bit more.
